

SELF-VENTILATED, ERGONOMIC FOOTWEAR AND SOLE**OBJECT OF THE INVENTION**

5 The present invention relates to footwear and a sole
which said footwear comprises but which can be applied to
other types of footwear. On the one hand, the footwear offers
optimum performance from an ergonomic point of view adapting
itself perfectly to the user's foot irrespective of the
10 different relation between the length and width of said foot
due to an elastomeric sole or the like, generally obtained by
means of injection moulding, subsequently covered by means of
an insole and combined with the corresponding upper to finish
the footwear, and on the other hand allowing for inner
ventilation which is automatically generated on walking, also
15 improving comfort in this aspect.

Thus, the object of the invention is to obtain footwear
offering the user thereof greater comfort, both from the point
of view of the comfortable adaptation to his feet and also the
ventilation thereof, and a sole which in the area
20 corresponding to the sole of the foot has a high degree of
elastic deformability in the transverse direction in order to
enhance the comfort of the footwear for the user, anatomically
adapting itself to the feet thereof, irrespective of their
greater or lesser width.

25 BACKGROUND TO THE INVENTION

Within the scope of footwear, and more specifically of
soles for same, one of the solutions normally used is that in
which the sole is obtained by means of injection moulding from
elastomeric materials.

30 The outsoles are manufactured according to pre-
established sizes, based on a stepped table of foot lengths,
such that any person can find shoes in the market with a size
suited to the length of his feet.

The same does not apply regarding the transverse
35 elevation, as this is usually fixed for a certain type or

design of footwear, which as is known means a serious problem for those having "wide feet", who are forced to bear the discomfort of shoes which "pinch them" or are forced to use a larger size than they should depending on the length of the foot, because evidently as the size of the footwear increases, the width thereof increases in parallel.

The solution to this problem is to use lasts of different widths, this evidently having very negative effects from an economic point of view, specifically from the point of view of manufacturing and distribution costs.

A less encumbering solution is to use uppers based on soft materials, which partially resolves the problem, especially when the user's feet are not much wider than normal, but this leads to a deformation of the footwear making it lose its original appearance completely after a short period of use.

On the other hand, due to their very nature, these elastomeric soles offer virtually no degree of transpiration, such that they retain the user's body sweat, it thus being desirable to have an inner ventilation of the footwear for evaporating the sweat as it is produced.

Footwear provided with means of inner ventilation exists on the market, but the solutions adopted up to the present are structurally complex and functionally rather ineffective, thus their practical use is determined more by advertising propaganda than by a real effectiveness to that respect.

DESCRIPTION OF THE INVENTION

The footwear and the sole proposed by the invention resolves in a fully satisfactory manner the problems set forth hereinbefore in the two aspects discussed, so that in addition to offering optimum performance from the ergonomic point of view, perfectly adapting themselves to the anatomy of the user's foot, it allows said ventilation which occurs automatically when walking.

To that end and more specifically, the footwear of the invention, based on the use of an elastomeric sole obtained

for example by means of injection moulding, combines special features of said sole with other features affecting its complementary upper and allowing the effects sought to be obtained.

5 Specifically, the sole is provided with longitudinal grooves in the area corresponding to the sole of the foot, that is, extending between the toe and the start of the waist, operatively arranged both on its upper or inner side and on its lower or outer side, which grooves affect about half the
10 thickness of the sole in this area, said plurality of longitudinal grooves, preferably of an arched path, that is parallel to the side edges of the sole in its area of location, with the special particularity that the grooves of its upper side are transversely staggered with respect to those of the
15 lower side, such that this area of the sole configures a type of bellows allowing elastic deformation in the transverse direction of the sole in said area of the sole of the foot due to the pressure exerted by the foot depending on the width of the latter which is obviously where the problems derived from
20 "wide feet" occur.

 Accordingly, the original dimensions of the width of the sole in the area corresponding to the sole of the foot are maintained when the user has a normal foot width, but faced with the needs of a wider foot an easy transverse dilation of
25 the sole in this area of the sole of the foot occurs, that is, a widening thereof occurs, suiting it to the needs of the foot, conferring the footwear with a high degree of comfort.

 This greater comfort can be extended to any type of user because the same elastic deformability occurs under normal
30 conditions, making the footwear much more comfortable as it has a "softer" sole without changing the material.

 Complementarily, the upper which is closed in the lower portion and, as is usual, by means of an insole, also incorporates in the area of the sole of the foot an elastic
35 body, which due to its own nature favours the elastic

deformation in the transverse direction of the footwear in this repeatedly said area of the sole of the foot, and which further incorporates openings suitably distributed for the entrance and exit of air. A chamber is thus created between the elastic body and the sole the volume of which changes upon walking due to the expansion and contraction of the elements making it up, which volumetric variation leads to a "lung" effect such that the air enters and exits said chamber, causing the sought ventilation of the foot in the area of the footwear which is the most problematic to that respect, that is in the closed area of the sole of the foot, because ventilation usually occurs in the heel area through the foot access opening.

DESCRIPTION OF THE DRAWINGS

To accompany the description being made and for the purpose of better understanding the features of the invention, according to a preferred practical embodiment thereof, a set of drawings is attached as an integral part of said description in which, with an illustrative and non-limiting character, the following is shown:

Figure 1 shows a schematic perspective illustration of a sole for footwear carried out according to the object of the present invention, showing the upper side thereof.

Figure 2 shows an illustration similar to the previous figure, but in which the lower side of the sole is shown.

Figure 3 shows an exploded plan view of a self-ventilated ergonomic footwear carried out according to the object of the present invention in which both the upper of the footwear and the sole thereof show the sides through which they must be adapted and fixed.

Figure 4 shows a cross section detail of the assembly represented in the previous figure, duly assembled.

PREFERRED EMBODIMENT OF THE INVENTION

In view of Figures 1 and 2, it can be seen how the sole (1) proposed by the invention is, like any conventional sole,

made up of a one-piece body with the classic sections corresponding to the sole of the foot, to the waist and to the heel, these sections being able to adopt, particularly as regards the outer side shown in Figure 2, any type of surface finish or configuration in accordance with the design provided for the sole.

The invention centres on the fact that the sole (1) incorporates on its inner side and in the area corresponding to the sole of the foot, a plurality of uniformly distributed longitudinal grooves (5) which, in the practical embodiment shown in the drawing, are five in number, but this number can vary without this affecting the essence of the invention, which grooves are preferably curved and parallel to the side edge and next to the body of the sole.

Said grooves (5) of the upper side of the sole are complemented with other lower grooves (5') which must necessarily be arranged in an alternating manner with respect to the upper grooves (5), as can be observed perfectly in Figure 4, for which reason there must be a higher or lower number of lower grooves than upper grooves (5), the number being greater in the chosen practical embodiment, specifically six.

The depth of the grooves (5) and (5'), in relation to the thickness of the sole in this area of the sole of the foot must be such that it affects about half of said thickness in order to obtain the bellows-type structure shown in Figure 4 which, providing the sole with the suitable formal stability, nevertheless allows that, in the specific case of a "wide feet" user, the sole can be elastically deformed in the sense of transverse widening to perfectly adapt itself to the dimensional demands of the foot as previously stated.

Obviously this elastic deformation of the sole (1) in the area corresponding to the sole of the foot is not obstructed by the classic insole internally covering or by the upper of the footwear, because both are easily deformable.

Evidently said grooves (5) and (5') affect neither the waist nor the heel given that these areas of the footwear do not usually present any problems for people with "wide feet", in which the excessive width of the feet occurs exactly in the area corresponding to the sole of the foot.

In view of Figures 3 and 4 it can be seen how the footwear proposed by the invention is formed, like any conventional footwear, by means of the combination of a sole (1) and an upper (2), the latter having a lower inner perimetral edge (3) for its adaptation and fixing to the sole (1) by any appropriate means, the classic insole (4) suitably isolating the user's foot from the sole (1) and which can optionally be covered by another insole for decorative purposes, being arranged on the inside of the upper (2).

Complementarily in the upper (2) and also in the area corresponding to the sole of the footwear, specifically under the insole (4), a laminar elastic body (6) is arranged, suitably fixed at its contour to the upper (2), for example, to the previously mentioned perimetral edge (3), which elastic body (6) allows and favours deformation in the transverse direction of the footwear, and which according to a preferred practical embodiment will be stiffened by means of a longitudinal band (7) and a pair of transverse end bands (8-8'), perfectly visible in Figure 1, fixed both to the elastic laminar body (6) and, where appropriate, to the edge (3) of the upper, these bands (7-8) having the purposes of suitably stabilizing the elastic body (6), defining therein two independent side deformation areas.

On the other hand, the thickness of these bands (7-8) favours the arrangement of the variable volume chamber (9) between the elastic body (6) and the sole (1), the volume of which will decrease when supporting the foot on the ground, the air exiting said chamber through a plurality of openings (10) arranged in the bands (7) and (8) with air penetrating into the useful inside of the footwear, whereas an increase in

the volume of the chamber (9) and an aspirating effect occurs when lifting the foot from the ground and due to the elastic recovery of the body (6).

5 Therefore, and according to the described structure, the
grooves (5-5') of the sole (1) and the elastomeric nature
thereof, as described, allow the elastic deformation in the
transverse direction of the sole so that the footwear
comfortably adjusts to the user's feet, irrespective of the
width thereof, whilst at the same time the chamber created
10 between the elastic laminar body (6) and the sole itself,
together with the openings (10) for communicating with the
inside of the footwear, generate a ventilation in the latter,
with a "lung"-type movement of air maximally increasing the
comfort of the footwear as a whole.
